# 1.0 INTRODUCTION

In April 2005, Alberta Finance, Statistics conducted a Spatial Price Survey on behalf of Alberta Economic Development and Alberta Education. Similar surveys were conducted in April of 2001 for 10 Alberta communities and June of 2003 for 34 Alberta locations. The most current population statistics for each location are provided in Table 1.

This report presents the survey findings for 37 Alberta communities, with Edmonton designated as the reference base (i.e. Edmonton =100.0).

The following sections of this report introduce the concept of price indices, describe how the indices relate to the data presented; detail the survey design and methodology employed; and provide an analysis of the Edmonton-based comparisons. A detailed list of food and non-food categories is presented at the conclusion of this report.

**Table 1**  
**2004 ALBERTA POPULATION BY COMMUNITY**

COMMUNITY	POPULATION	COMMUNITY	POPULATION
Athabasca	2,415	Lethbridge	72,717

\*\*Figure represents the Municipality of Jasper with shadow population = 351.

## 2.0 BACKGROUND

This section provides a brief background describing the “aggregate” or “complex” price index employed in this survey.

### 2.1 SPATIAL PRICE INDICES

A price index is a ratio of two numbers: a comparative price and the base price to which it is compared. Indices are tools to measure the differences in one price relative to the other and may be constructed to measure price differences for individual commodities, for a basket of goods, or for a group of commodities. An index that measures differences in individual commodities is referred to as a “price relative” or a “simple price index” whereas an index that measures differences between a group/basket of goods generally represents an “aggregate” or “complex” price index.

The value of the base is generally established at 100.0 with all other prices expressed in terms of this base. An index with a value greater than 100.0 indicates that prices are higher than the base price or vice versa and allows for comparison and interpretation in percentage terms. For example, an index of 120.0 indicates a twenty-percent difference between the base point and the index value inferring that prices are twenty percent higher than the reference base. An index of 90.0 would signify prices are ten percent lower.

There are several different types of price index measurements. The price index produced for this publication is a **spatial price index**, which is location-based and compares the prices of one or more commodities between various locations at a

**specific point in time.** Spatial indices may be used to 1) compare one reference location and several communities, and 2) measure price differences between any two communities. For the purpose of this survey, only comparisons with one reference location (Edmonton) and several communities can be made. Since a spatial index does not measure price movements over time but measures price differences between communities, price levels within the comparable communities are always collected at one point in time in order to remove any time-related biases.

For the purposes of this survey, aggregate or complex price indices are generated.

## 3.0 METHODOLOGY

### 3.1 PURPOSE OF SURVEY

The purpose of the 2005 Alberta Spatial Price Survey is to measure price differences between selected Alberta communities and Edmonton for a specific basket of goods and services at a specific point in time. The price differentials are measured through the construction of spatial price indices for the selected survey communities.

### 3.2 SURVEY DESIGN & CONTENT

The following steps are required to construct a spatial price index:

1. The survey communities must be chosen;
2. A basket of goods and services to be surveyed must be selected; and
3. The prices of these goods and services must be collected during a specified time period in each community.

For the 2005 survey, sponsors selected 37 Alberta communities, with Edmonton designated as the reference location.

The goods and services used for this survey are similar to the survey items used by Statistics Canada to construct monthly Consumer Price Indices for Alberta cities. A total of 302 goods and services form a subset of Statistic Canada's basket of survey items and were selected based on the following criteria:

1. The items comprise those goods and services perceived to be regularly purchased by Alberta consumers (based

on the Survey of Household Spending) living in cities, and medium/small-sized towns.

2. The items are judged to be available in most of the selected communities to allow price comparability.

Each item is associated with a retail price such that a sum of money must be paid by a consumer in order to purchase a specific quantity and quality of a good or service.

With the survey locations and a basket of goods and services selected, a pricing period is then established. To minimize time-related biases, prices in all centres were collected within a two-week period from April 25 to May 6, 2005.

To ensure accuracy and consistency in the pricing of the 302-item basket of goods and services, it was essential that all the items be carefully matched across all communities. In order to facilitate this process, pricers were provided with specification sheets containing a detailed description of each article to be priced, including brand name, quantity and size. If the specified brand was unavailable, a list of alternatives was also provided. Survey personnel were asked to price one of the specified brands and record other details such as size and style number.

If none of the specified brands were available, pricers were asked to price a close substitute and provide a detailed description of the item. This substitute item was then priced in Edmonton to ensure comparability between the two communities. In this manner, item consistency was assured between Edmonton and each community but could differ among communities for some articles. If a reasonable substitute was unavailable in some communities, these articles were excluded from the survey list for those particular centres.

### 3.3 SPECIAL PRICING PROCEDURES

Certain goods and services could not be directly priced in the field through retail or service outlets found in the survey communities. Items that required special pricing procedures included monthly housing payments, rental costs, property taxes, and utilities such as natural gas, electricity, water, garbage disposal, and sewage charges.

Calculating monthly housing payments and mortgage interest costs for each community required several steps. Housing prices were first collected in each community for several styles of single detached residential dwellings. A variety of secondary data sources such as Alberta Municipal Affairs, Royal LePage Survey of Canadian House Prices, and local real estate boards or agencies provided and/or confirmed housing prices for each community. Several home details such as age of dwelling, square footage of home and lot, amenities, the number of bedrooms and bathrooms, etc. were taken into consideration in pricing a similar home in Edmonton. A survey of the average mortgage down payment and mortgage rates for a one, three and five-year term as of April 2005 was conducted. The mortgage rates were blended to calculate an average mortgage interest of 4.739 per cent as of April 2005. This rate was then applied in combination with a five percent down payment and 25-year amortization period to determine mortgage interest costs for each community.

Average monthly rental costs for each location were obtained through a survey and supported with statistics gathered by local real estate boards, local property management companies, Alberta Seniors and local/municipal government offices.

To derive the average monthly property tax bill in each survey community for April 2005, Alberta Municipal Affairs and local/municipal government offices provided residential mill rates for each community. Residential mill rates were applied to the average housing price surveyed in each community to derive an average monthly tax bill.

In order to calculate monthly natural gas, electricity, water, sewage, and garbage disposal charges per household in each of the survey communities, an average monthly household consumption figure was obtained for each item from local/municipal government offices and/or suppliers of each utility. The consumption figure was then multiplied by the applicable rates to derive typical household costs in each community. Utility suppliers provided delivery charges, consumption charges, administration or billing charges, municipal franchise fees, and rebates that were applied to each location where applicable.

### 3.4 WEIGHTING FACTORS

Price indices may be calculated as weighted or not weighted. The disadvantage of “unweighted” price indices is that their relative importance to the consumer is not taken into consideration, therefore equal weight or “importance” is assigned to all goods and their prices. By assigning equal weight to various goods, a distortion of the index can be created. For example, a change in the price of milk would not carry the same significance to a consumer as would a change in the price of meat. If these goods were given equal weight, the resulting change in the overall index would not be accurately measured in terms of their actual consumer impact.

In order to avoid this problem, weights have been assigned to all goods and services priced in the 2005 Alberta Spatial Price Survey. Weights are provided by Statistics Canada and are derived from Survey of Household Spending data. Assigning a weight to each survey item serves to: 1) ensure that goods or services reflect their relative importance to the consumer, 2) correctly calculate a spatial price index, and 3) avoid exerting undue influence on the spatial indices creating a distortion on the true magnitude of the overall price difference between communities.

The 2005 Alberta Spatial Price survey uses a subset of the basket used by Statistics Canada that determines monthly the Consumer Price Index (CPI) for Edmonton and Calgary. The Statistics Canada basket is based on the expenditures of a target population in a certain reference period, i.e. 2001. As such, the basket for the 2005 Alberta Spatial Price Survey is weighted according to the April 2005 CPI expenditure weights for Alberta and accounts for 84.7 percent of the weighted CPI basket. A normalized weighting distribution for the 2005 Alberta Spatial Price Survey basket of goods and services is presented in Figure 4 located in the Appendices. The chart indicates that the weighting pattern used for each aggregate index in the 2005 Alberta Spatial Price Survey is relatively consistent with the 2001 CPI basket of goods and services' weight distribution.

### 3.5 INDEX CONSTRUCTION

For the purpose of this survey, an aggregate price index was generated using prices observed for 302 commodities in each of the 36 communities. Table 6 in the Appendices outlines the basket of goods and services

used to generate the Edmonton-based indices. Several items listed in Statistics Canada's CPI basket were excluded due to the lack of availability or comparability of these items in some survey locations. For each survey community, a total of twenty aggregates are produced which include three aggregate and seventeen sub-aggregate indices. The indices are provided in Tables 2 through 5 found in the Appendices.

The aggregate indices constructed for each survey community include:

1. An all-commodity index (up to 302 items);
2. A food index (up to 109 items);
3. A non-food index (up to 193 items); and
4. A commodity category index (up to 45 items).

Seventeen category-specific indices form subsets of the aggregate food and non-food indices.

The specific food indices are:

- Dairy Products
- Fats and Oils
- Cereals and Breads
- Processed Fruits and Vegetables
- Fresh Fruit and Vegetables
- Meat, Fish, Poultry and Substitutes
- Frozen and Packaged Food
- Restaurant Meals

The non-food indices are:

- Personal Care Products
- Household Supplies
- Household Services
- Household Equipment
- Recreation and Leisure
- Transportation
- Clothing
- Shelter
- Utilities

More complex indices are needed to capture, in a single value, several commodities per location. The most common method of simultaneously comparing several prices between different communities is to compare their averages. For example, suppose prices have been observed for three specific goods in two communities where Location A serves as the base community and Location B is the comparative community. The price of good 1 in Location A is denoted as  $P_{A1}$ , and in Location B as  $P_{B1}$ . The price ratio for good 1 would therefore be  $(P_{B1}/P_{A1})$ ; for good 2:  $(P_{B2}/P_{A2})$ ; and for good 3:  $(P_{B3}/P_{A3})$ .

To construct an aggregate price index that compares the average of the price ratios between communities, the price ratios are summed and then divided by the number of entries in the sum. In order to derive an aggregate index value, the average price index of the three commodities is multiplied by 100. The construction of this aggregate price index is:

Aggregate Price Index =

$$\frac{[(P_{B1}/P_{A1}) + (P_{B2}/P_{A2}) + (P_{B3}/P_{A3})]}{\text{Number of Ratios} \times 100}$$

An aggregate price index of 145.0 implies that the prices of the selected goods in Location B are 45 per cent higher than in Location A. Conversely, a price index of 97.0 indicates that prices are 3 per cent lower in Location B than in Location A.

Price ratios are constructed and compare each community with Edmonton. These ratios are then weighted and summed to calculate the various indices. More specifically, the process in deriving the index calculations for the 2005 Alberta Spatial Price Survey is as follows:

**Step 1: Ratio of Prices:**

$$\frac{\text{Average Price of Item in Community A}}{\text{Average Price of Item in Edmonton}}$$

**Step 2: Weighted Ratio:**

$$\text{Ratio of Prices} \times \text{Item Weight}$$

**Step 3: Category Index:**

$$\frac{\sum (\text{Weighted Ratio for a Category}) \times 100}{\sum (\text{Item Weights for Category})}$$

### 3.6 DATA COLLECTION

Employees of Alberta Finance, Statistics surveyed items through personal visits to retail and service establishments in each survey community. Where possible, staff was hired from each of the local communities to conduct the pricing. To ensure a representative sample of prices, survey personnel collected a minimum of three prices per item in each community. Pricers were asked to disregard special or sale prices on items and to record only regular prices without GST to improve data reliability and confidence.

### 3.7 DATA PROCESSING

Data analysis was performed using SAS software. Extensive data editing and verification procedures were utilized to ensure item consistency between the base location (Edmonton) and the other survey communities.

### **3.8 GUARANTEE OF CONFIDENTIALITY**

The survey was conducted in accordance with The Statistics (Bureau) Act of Alberta, Chapter S-18 of the Revised Statutes of Alberta, 2000, whereby confidentiality is guaranteed under this Act.

### **3.9 CAUTIONARY NOTES**

The reader should note that when using the indices in this publication, the following assumptions and limitations should be kept in mind:

1. The purpose of this survey is to produce spatial price indices that compare price levels in selected communities to those in Edmonton at a specific point in time. The indices constructed for this publication cannot be compared over time to determine price changes.
2. The expenditure weights of the 302-item basket of goods and services are based on the weighting pattern for Alberta from Statistics Canada's Survey of Household Spending data. Since expenditure weighting patterns are unavailable for other survey communities, they are assumed to be the same as those used for Alberta. It is probable that in communities outside Edmonton, consumption and expenditure weighting patterns differ through the influence of local factors such as customs, tastes, incomes and product availability.
3. The 2005 Alberta Spatial Price Survey does not produce cost-of-living indices for the 37 selected communities. The present methodology employed does not incorporate many of the variables necessary to construct such an index. A

cost-of-living index requires complete information about a person's tastes and consuming habits and measures price changes that are experienced by consumers in maintaining a constant standard of living. In this situation, consumers would normally switch between products as the price relationship of goods changes and may choose the cheaper of the interchangeable products. The 2005 Alberta Spatial Price Survey utilizes a fixed basket of goods and services to derive the price indices.

4. Variations in the weighting pattern and number of items surveyed arise due to the lack of availability and comparability of certain items in some communities.

## 4.0 ANALYSIS OF EDMONTON-BASED COMPARISONS

The results of the 2005 Alberta Spatial Price Survey are presented in Tables 2 to 5 and Figures 1 to 3 (Figures located in Appendices). For all indices, Edmonton prices serve as the reference base with each Edmonton index assigned a value of 100.0. All other indices reflect community prices relative to this base index. For example, communities with an index of 100.0 for any component category or for the total basket of goods and services experience prices equivalent to those in Edmonton. Indices of less than 100.0 indicate community prices were lower than the base community while centres with indices greater than 100.0 recorded prices higher than in Edmonton. As a note, the number of items priced and the weighting patterns can vary between commodity categories for each community surveyed due to lack of availability and comparability of certain items in some communities.

### 4.1 ALL COMMODITY INDICES

Table 2 and Figure 1 present the aggregate **All-Commodity Indices** for each of the 37 survey communities. Included in Table 2 are the overall weighting patterns for each community and the number of items surveyed.

For the 2005 survey, Barrhead recorded the lowest price index of 93.1, the result of a

low Shelter index. The three highest all-commodities indices were reported for Canmore, Jasper and Fort McMurray at 116.5, 115.9 and 115.7 respectively. Canmore's high all-commodity index may be attributed to its high sub-aggregate indices for Household Equipment and Shelter. In addition, five communities (High Level, Grande Prairie, Calgary, Slave Lake, and Peace River) were observed to have higher all-commodity indices in comparison to the Edmonton base. Indices for these locations ranged from 101.8 to 103.3.

### 4.2 FOOD INDICES

Overall **Food Indices** are provided in Table 3 and Figure 2. The indices range from 93.0 (Cold Lake) to 110.7 (Jasper). Jasper's eight food subcategories ranged from 106.3 to 120.3 with the highest value representing Cereals and Breads. Although Canmore reported the highest all-commodity index, this location had three food sub-aggregate indices lower than Edmonton.

### 4.3 NON-FOOD INDICES

Table 4 and Figure 3 present the **Non-Food Indices** for each community. When compared to Edmonton, eight communities reported higher non-food indices ranging from 102.1 (Peace River) to 120.4 (Canmore). These communities include Peace River, Slave Lake, Grande Prairie, High Level, Calgary, Jasper, Fort McMurray and Canmore. Barrhead exhibited the lowest non-food index of 91.1 and had the lowest Shelter commodity index of 69.4 in comparison to other surveyed communities. In addition, Canmore reported indices greater than Edmonton's base of 100.0 for eight of the nine specific non-food categories.

In general, the higher non-food indices may be attributed to the significant influence exerted by the shelter component in the spatial price survey. While the shelter category accurately reflects the cost of housing in each community for similar structures, many qualitative aspects such as location, age of dwelling, finish, etc. may not be fully accounted for in determining real estate values for each of these communities. For this reason, caution must be exercised in generalizing trends for individual commodity categories based on the aggregate indices for the non-food component of this survey.

#### **4.4 COMMODITY CATEGORY INDICES**

Table 5 provides a breakdown of both the food and non-food components into their seventeen sub-component commodity categories. The highest Shelter index of 169.8 was reported for Canmore followed by Fort McMurray and Jasper at 169.7 and 137.7, respectively. The community of Medicine Hat possessed the lowest Utilities price index of 74.1 in comparison to other surveyed communities that ranged from 90.5 (Wainwright) to 123.1 (High Level).

Figure 1 in the Appendices illustrates that approximately 59% of the total survey basket weight is comprised of food, shelter, and transportation. In addition, recreation, education and reading account for 13.9% of the total basket of goods and services used in the survey.

In comparison to Edmonton, several surveyed communities reported higher sub-aggregate price indices for the categories of Household Supplies and Household Equipment. Lower price indices were

observed for the commodity category of Household Services.

Although these indices are accurate, they may not adequately represent many qualitative differences.
